POST-PACKAGE PASTEURIZATION OF PACKAGED WHOLE-MUSCLE PRODUCT

L. Vinnikova, doctor of techn. sciences, Professor, O. Synytsia, postgraduate student, Odessa National Academy of Food Technologies, Odessa

Abstract. The study considers a problem of repeated contamination of delicious products, ready for consumption. The aim of the work is to study the repeated thermal processing of a ready vacuum-packed whole-muscular meat product for inhibiting a surface microbiota.

Today it is urgent for the meat industry, because it influences safety and quality, and also limits a storage term of a product. After bringing a meat product to culinary readiness by thermal processing, it has an unessential amount of microbiota. Microorganisms, including pathogenic and conventionally pathogenic ones, fall on a product after its cooking at cutting, preparation to package and at the package stage itself. Microbiological contamination of a ready meat product results in fast spoilage and is a serious problem for producers, because the microbiota growth shortens its storage life. In its turn, it results in a refuse of a consumer to buy this product and great economic losses for producers.

The study is directed on a possibility of solving a problem of contamination of a whole-muscular delicious meat product. The solution is in package of a ready product under vacuum and short-term heating at a high temperature.

The work is devoted to the complex study of an influence of repeated pasteurization on safety and quality of a product. There was studied an influence of the repeated thermal processing (post-pasteurization) on microbiological, physical-chemical and also organoleptic parameters of a delicious meat product.

The special attention is paid to an influence of post-pasteurization regimes on a microbiological condition of studied samples. Studies of a total amount of microbiota and also the presence of sanitary-representative microorganisms were conducted.

It has been proven, that the use of post-pasteurization essentially inhibits a number of microorganisms, and also doesn’t influence physical-chemical parameters outlook of a product and organoleptic characteristics.

Based on studying an influence of post-pasteurization, it has been established, that inhibition of a microbiota essentially influences safety and prolongs the storage term of a product.

Key words: post-pasteurization, thermal treatment, microbiota, delicious meat products, food safety, shelf life.
goes unanswered and is a serious problem for producers, as it appears, product quality and safety are the most important aspects for the purchase decision of consumers. It is also important for the producer to ensure the best possible conditions for the production and storage of the products.

In the production of meat products, it is necessary to take into account factors such as the presence of microorganisms that can cause spoilage and affect the quality of the final product. These microorganisms are present at all stages of the production process and can affect the quality of the final product, both from a microbiological and organoleptic point of view.

One of the ways to improve the microbiological condition of meat products is the use of repeated thermal processing of vacuum-packed products mostly eaten without additional thermal treatment. This can ensure the shelf life of the product and prevent the growth of microorganisms and the development of a sour odor.

The use of repeated thermal processing can also be effective in the production of meat products with high nutritional value and high demand among consumers. These products are mostly eaten without additional thermal treatment, which limits the storage life of the product.

In conclusion, the use of repeated thermal processing of vacuum-packed meat products can be an effective way to improve the microbiological condition and prolong the storage life of meat products, which is extremely important in the production and sale of meat products.
Analysis of recent research and publications. In-package pasteurization of ready-to-eat products can be the final stage in destroying vegetative microbiota and be an effective method of preventing product spoilage [23].

Effect of thermal treatment and high pressure on ready-to-eat boiled sausages for inhibiting microbiota and extension of the product shelf life were studied in [24]. Samples of boiled sausages in a vacuum package were kept in a water bath at 80 °C for 15 min. after temperature in the product reached 75 °C. High pressure treatment was carried out at 600 MPa. Studies have shown that pasteurization and high-pressure processing can be used to increase the product safety and extend its shelf life. Studies have also shown that pasteurization is more effective than high-pressure treatment.

The results of studies in [25] demonstrate effectiveness of using thermal treatment to extend shelf life of Viennoise sausages. For example, to extend shelf life up to 4 times, thermal treatment of ready-to-eat vacuum-packed sausages at a temperature of 80 °C for 20 min. was used. Studies on the use of thermal treatment of ready-to-eat sausage products were also carried out in [26]. The study results indicate effectiveness of pasteurization in relation to microbiological safety.

Possibility of extending shelf life of boiled sausages using repeated pasteurization was studied in [27]. To extend shelf life of boiled small sausages up to 72 days, repeated pasteurization at a temperature of 85–90 °C for 15–20 minutes was used.

The use of pasteurization of cooked chicken thighs individually packed in a vacuum bag was effective to reduce number of microorganisms including *Listeria innocua* [28].

In [29], vacuum packed sausages heat treated to a core temperature of 90 °C and 100 °C were edible for 9 days at a storage temperature of 31 °C.

Experiments with small sausages which were grilled, vacuum packed and then heated at 95 °C for 5 min. in a steam chamber were conducted in [30]. Repeated thermal treatment of packaged productssubstantially extended their shelf life. However, thermal treatment of sliced sausage in these conditions has destroyed the product structure.

Appearance of samples of baked and vacuum-packed turkey heated at 95 °C has changed, however the shelf life was 4 weeks longer than that of the control sample.

Studies of pasteurization of already-to-eat product that were carried out with samples having protective covering (encapsulation) have shown no organoleptic changes. However, there is a significant problem of repeated processing non-encapsulated meat products because of possibility of alteration of their appearance, structural and qualitative characteristics under long influence of heat [31].

It is clear from the literature analysis that the issue of thermal treatment of non-encapsulated whole-musclemeat gourmet has not been resolved.

The aim of the work is to estimate a possibility of inhibiting a surface microbiota of a ready deli-cious meat product, packed in vacuum by pasteurization, without changing organoleptic characteristics.

To achieve this objective, the following tasks were set:

– to experimentally determine rational temperature and time conditions of post-pasteurization;

– to determine safety and quality of the product after post-pasteurization based on microbiological, physical-chemical and organoleptic characteristics.

The studying procedure is based on the following generalized knowledge: an influence of thermal processing on microorganisms and also quality, structural-mechanical and organoleptic parameters of a product [2; 32; 33]; an influence of vacuum package on the microbiota life activity in a meat product [34; 35]; thermostable properties of packing films.

Materials and methods of research. Samples of smoked-boiled meat «Balyk vintage» of the highest sort were used in the study. All samples were produced at PE «GARMASH» (Ukraine, Odessa region). The samples were cooked of 100% meat of spine-lumbar muscles of pork semi-car cass.

All raw and ready materials, used in the study, corresponded to actual standards of Ukraine in the aspect of quality and safety.

Experiments. After bringing the product to culinary readiness, it was cooled to temperature 6–8 °C, cut in pieces of 100 g and packed under vacuum in multi-layer polymeric films with width 95 microns, produced by “Orved” (Italy). Package was realized on the vacuum-packing machine, produced by “Cryovac” (Switzerland).

The experimental samples, packed in vacuum, were subjected to post-pasteurization in the elec-tric digester SVC-14, produced by Sannmic S. L. (Spain). After post-pasteurization, the samples were cooled to temperature 6–8 °C and kept in the refrigerator Liebherr (Germany) at temperature 4 °C during the whole term.

Together with the experimental samples, subjected to post-pasteurization, balyk samples in a vacuum...
package without post-pasteurization (control samples) were kept under equal conditions in the refrigerator. All samples were kept in the refrigerator during 35 days.

The experimental studies were three- and fivefold repeated. The obtained results were presented in units of the international system CI [36; 37].

**Results of the research and their discussion.** During the study there were determined main microbiological, physical-chemical and organoleptic parameters of the experimental and control samples of whole-muscular delicious meat products.

Meat products of 100 g in a vacuum package were heated at temperature 90 °C during 1 min (sample 1), 2 min (sample 2) and 3 min (sample 3).

Table 1 presents the results of the total number of microorganisms (MAFAnM) in the control sample, and also the number of microorganisms in the experimental samples at 1 day of storage.

Table 1 testifies that the use of pasteurization of the ready delicious meat product, packed in vacuum, essentially inhibits the microbiota.

There were studied the sanitary-representative microorganisms, such as sulfite-reducing clostridia, Salmonella, St. aureus, and also bacteria of the colon bacillus group. The results of these studies demonstrated that no listed microorganisms were found in the product.

The microbiological studies were conducted during the whole storage term in each 7 days.

During the storage process there was observed the intensive growth of microorganisms in the control sample, and at 28 day of storage the norm of MAFAnM was essentially exceeded [18].

The growth of microorganisms in experimental samples 1 and 2 was less intensive, but at 28 day it exceeded the norm of MAFAnM along with the control. During the storage process sample 3 had the inessential growth of the microbiota and even at 35 day didn’t exceed the normative index of total semination.

The sanitary-representative microorganisms were not found during all 35 days of storage in the control and experimental samples.

The effect of thermal processing has the influence on all components of the meat product and can change its outlook and structure [15]. The aim of our work was to diminish the number of microorganisms without changing organoleptic indices of the product. At the same time the storage term of the product is determined by not only microbiological parameters, but also by organoleptic characteristics. The sour-milk bacteria, such as: Lactobacillus, Carnobacterium and Leuconostoc mainly dominate in the product, packed under vacuum. The presented bacteria produce acids: lactic, acetic and formic ones and influence the product taste [20].

The studies of the organoleptic parameters testify to the fact that post-pasteurization doesn’t influence the outlook of the product and doesn’t cause changes of its organoleptic parameters.

During the process of storage the control sample at 28 day had spoilage signs, namely the sour smell. Control sample 3 didn’t have any outlook changes and also taste and smell ones, even at 35 day of storage.

The studies of pH and mass share of moisture demonstrated that post-pasteurization has no influence on the concentration of nitrogen ions and doesn’t cause free moisture release from the product.

**Conclusions:**

1. Inhibition of the microbiota of the ready whole-muscular delicious meat product, packed in vacuum, has been proven.
2. It has been established, that post-pasteurization essentially improves the microbiological condition of the product.
3. Temperature-temporal regimes of repeated pasteurization don’t cause changes of the product outlook.
4. It has been proven, that the product, subjected to post-pasteurization, has more storage term.
